# The trust problem

Cryptocurrency transactions offer many advantages, but they also present one fundamental issue: trust.

- We don't always know who we are paying or who we are selling to.
- We have no guarantee that the goods, service, or payment will be delivered.
- There is no single flow that allows staged payments to be managed securely.

## > Escrow

An escrow system locks the funds in a wallet supervised by the platform. The funds remain locked until both parties provide final confirmation.

## > Milestone System

The Milestone system allows a payment to be split into multiple stages, providing greater protection for the money being sent. The item being sold is uploaded and remains locked until the corresponding milestone is paid.

## > Online Profile

The system includes an online profile built from reviews and account data. AI helps assess risk and highlight safer transactions.

# Use cases

MilestonePay can be used in different contexts, from small everyday payments to higher-value transactions.

- Payments between individuals and small occasional purchases.
- Commissioned orders with milestone-based payment release.
- Higher-value transactions with greater control over the process.
- Integrated chat and online profiles to define agreements and manage potential issues.

The goal is to make digital payments simpler, safer, and more automated, even for people who use the service only occasionally.

# How It Works

# Database and security

*Our escrow system is built around security and reliability. To achieve this, the platform relies on the following projects.*

*Used as decentralized storage for files, documents, and evidence linked to milestones.*  
*Each item can be connected to the agreement through a verifiable reference that is difficult to alter.*  
*It reduces reliance on centralized servers and makes evidence more reliable during potential disputes.*

- Used to manage the metadata of agreements, milestones, and evidence associated with the contract.*
- It makes data easy to organize and query without relying on a traditional Web2 database.*
- The information remains linked to the wallet and can be retrieved and verified throughout the entire agreement lifecycle.*

*Used as decentralized storage for files, documents, and evidence linked to milestones.*  
*Each item can be connected to the agreement through a verifiable reference that is difficult to alter.*  
*It reduces reliance on centralized servers and makes evidence more reliable during potential disputes.*

- Used as the blockchain infrastructure for running MilestonePay escrow smart contracts.*
- It manages locked funds, milestone status, and payment releases according to the agreed rules.*
- All key operations are recorded on-chain, making the process transparent and verifiable.*

# Security

## AI monitoring

AI monitors, verifies, and manages transaction security and reliability, helping users assess who they can trust before sending or receiving money.

### Payment security:

You don't need to rely on trust, because Milestone guarantees the integrity of the transaction.

### Human oversight

The process is fully automated, but a human operator can always review and intervene in the event of disputes or issues related to AI monitoring.
